Abstract:	Proximate composition (moisture, protein, fat, ash and carbohydrate components such as total carbohydrates, starch, amylose, dietary fibre, sucrose and fructose), pH and acidity were determined in eighteen wheat landraces cultivars from the Canary Islands in order to establish differences between them and contribute to their characterization. All the parameters analyzed showed significant differences between the analyzed cultivars; and also many parameters were affected by the specie and subspecie of wheat considered. The samples of <i>Triticum aestivum</i> had higher mean moisture, protein and fibre and lower mean starch, sucrose, and amylose concentrations than those samples belonging to <i>Triticum turgidum</i> . Low starch content and high fibre content could be due to the transformation of starch in resistant starch in the desiccation process of wheat grains. An important contribution to the daily intake of complex carbohydrates including fibre, as well as of protein and phenolic compounds was observed for the consumption of wheat.

16 **Abstract**

17 Proximate composition was determined in 19 wheat landraces cultivars from the Canary
18 Islands in order to establish differences between them and contribute to their characterization.
19 All the parameters analyzed showed significant differences between cultivars; and also many
20 parameters were affected by the specie and subspecie of wheat. *Triticum aestivum* had higher
21 mean moisture, protein and fibre and lower mean starch, sucrose, and amylose concentrations
22 than *Triticum turgidum*. Low starch content and high fibre content could be due to the
23 transformation of starch in resistant starch in the desiccation process. An important
24 contribution of complex carbohydrates including fibre, as well as of protein and phenolic
25 compounds was observed for the consumption of wheat.

26 **Keywords:** wheat landraces (*Triticum sp.*); proximate composition and physicochemical
27 parameters; nutrient intake

Wheat has been widely recognized as a symbol of the Mediterranean diet due to its nutritional relevance for the human diet. This cereal is an important source of proteins although with a relatively low biological value; complex carbohydrates, including dietary fibre; vitamins and minerals; and bioactive secondary metabolites as phenolic acids. Epidemiological studies suggest that consumption of whole grain and bran may help to prevent cardiovascular diseases, diabetes and certain forms of cancer (SLAVIN et al., 1997).

Modifications of the nutritional value can be of interest because of their high consumption in the population. Diets including enriched cereal products are encouraged by nutritionists in Western Europe in order to improve its nutritional contribution. Obviously, the selection of cultivars cereals, more rich from nutritional point of view, is also a good alternative to contribute in the improvement of the status nutritional of the population.

The project “Germobanco Agrícola de la Macaronesia” included in the Interreg III-B European program aims to characterize traditional cultivars to conserve the biodiversity of the agricultural cultivations in the Macaronesic region. Several papers have been published to chemically characterize traditional wheat cultivars (HERNÁNDEZ et al., 2011; HERNÁNDEZ RODRÍGUEZ et al., 2011). In this paper we determined proximate composition in different wheat landraces from Tenerife in order to establish differences between them and contribute to their characterization. Furthermore, this will help to select cultivars with best nutritional characteristics.

1. Material and methods

1.1. Wheat sampling

A total of 35 accessions corresponding to 19 cultivars belonged to *Triticum aestivum* (n=27) and *Triticum turgidum* (n=8), were provided for analysis by the Centro de Conservación de la Biodiversidad Agrícola de Tenerife (CCBAT, Spain). The description of the wheat samples,

56 including mean weight per grain and number of accessions for each cultivar is shown in Table
1
2 57 1. All the wheat cultivars used in the present study were traditional cultivars from Canary
3
4 58 Islands, except Vitrón cultivar which is a commercial cultivar.
5
6

7 59 All the wheat cultivars were experimentally cultivated in the same breeding ground
8
9 60 using the same cultivation methods and agronomic conditions on a collaborating farm of the
10
11 61 CCBAT (La Laguna). The wheat was sown in December 2004 and the harvest took place in
12
13 62 July 2005, when the wheat grains were in the same stage of maturation.
14
15

16 63 *1.2. Analytical methods*

17
18

19 64 The wheat samples (≈ 100 g) were separated in 5 sub-samples which were analyzed
20
21 65 independently, and each sub-sample was homogenized till formation of a fine and
22
23 66 homogeneous flour (Ika-Werke, Staufen, Germany).
24
25

26 67 All these analysis were carried out in duplicate, and the results expressed as fresh
27
28 68 weight (FW). Moisture (oven drying method), protein (Kjeldahl method, factor of 5.7), fat
29
30 69 (Soxhlet method), fiber (enzymatic-gravimetric method), pH, acidity (titration with NaOH
31
32 70 0.1N until pH 8.1, results were expressed as g citric acid per 100 g), ash (heated at 900 °C for
33
34 71 24 h), starch (enzymatic method) (A.O.A.C., 2006). Total phenolic contents were determined
35
36 72 by spectrophotometry at 750 nm after the colorimetric reaction with the Folin-Ciocalteu
37
38 73 reagent (Sigma, St. Louis, MO) (KUJALA et al., 2000). Gallic acid (Sigma, St. Louis, MO)
39
40 74 was used for the external standard calibration curve. Amylose was determined according to
41
42 75 the method of HOVENKAMP-HERMELINK et al. (1988), and the results were expressed as
43
44 76 g amylose per 100 g starch. Sugar determination was performed by HPLC following the
45
46 77 method described by RODRÍGUEZ GALDÓN et al. (2009).
47
48
49
50
51
52

53 78 *1.3. Statistics*

54
55

56 79 All the statistics were performed by means of the SPSS version 17.0 software for Windows
57
58 80 (SPSS Inc. Chicago, IL). Mean values obtained for the variables studied in the different

81 groups were compared by One-Way ANOVA (Duncan's multiple range) assuming significant
82 differences when $P < 0.05$. Correlation analysis was carried out to see relationships between
83 variables.

84

85 **2. Results and discussion**

86 Proximate composition, pH and acidity obtained in all the samples and differentiating them
87 according to the cultivar are shown in Table 1. There were important ($P < 0.001$) differences
88 between the wheat cultivars. Some differences in the chemical composition of wheat grains in
89 the data reported in the literature were observed, which might be associated with the genotype
90 and an environmental effect.

91 Moisture content was relatively constant in all the analyzed landraces (11.4-13.0%).

92 Moisture was inversely correlated with starch ($r = -0.459$, $P < 0.01$), fructose ($r = -0.430$,
93 $P < 0.01$), amylose ($r = -0.594$, $P < 0.01$) and pH ($r = 0.423$); and positively with fat ($r = 0.494$). All
94 the cultivars considered showed a mean pH inside a narrow interval between 6.33 and 6.65.

95 The lowest acidity was found in Raspinegro Canario landrace (0.116 mg/100 g), in contrast
96 with Marrueco and Español landraces, which had an acidity of 0.188 mg/100 g.

97 Carbohydrates represent the more abundant nutrient in wheat grain, ranging between 70.4%
98 and 75.5% for Colorado and Isla de Fuerteventura landraces respectively. The mean protein

99 concentration in all the landraces was 12.5%, which agrees with most of data published in the
100 literature (ANDERSON et al., 2013; DI SILVESTRO et al., 2012; KANDLAKUNTA et al.,

101 2009; RAGAEE et al., 2006, 2012; RANDHAWA et al., 2002; RANHOTRA et al., 1996;
102 SIKA et al., 1995). Colorado landrace had the highest protein content (14.2%), in contrast

103 with Vitrón landrace (10.3%), which presented the lowest protein percentage. All the wheat
104 landraces analyzed showed an ash content inside the interval 1.23% and 1.67%, whose values

105 were obtained for Vitrón and Español landraces, respectively. Ash mean content obtained in

106 this paper is in agreement with data reported in the literature (ANDERSON et al., 2013;
1
2 107 HAGER et al., 2012; KANDLAKUNTA et al., 2009; RANDHAWA et al., 2002; SERENA
3
4 108 & KNUDSEN, 2007). The fat concentration varied between 0.64% and 1.24% obtained in De
5
6
7 109 la tierra and Vitrón landraces, respectively. The fat content found by us was lower than the
8
9
10 110 data published by most of authors (ANDERSON et al., 2013; DI SILVESTRO et al., 2012;
11
12 111 HAGER et al., 2012; KANDLAKUNTA et al., 2009; RANHOTRA et al., 1996; SIKA et al.,
13
14 112 1995), although similar to those reported by RAGAEI et al. (2006). Total phenolic
15
16 113 concentrations were fairly constant among the landraces considered. Isla de Fuerteventura
17
18 114 landrace had the highest value (75.8 mg/100 g), and Arisnegro velloso de grano blanco the
19
20 115 lowest concentration (52.0 mg/100 g). Some investigators found higher concentrations than
21
22 116 those obtained in this paper (DI SILVESTRO et al., 2012; DINELLI et al., 2011), while other
23
24 117 obtained similar amounts of these compounds (ANDERSON et al., 2013; RAGAEI et al.,
25
26 118 2006).

31
32 119 Table 2 shows the results obtained in parameters related with the carbohydrates. Sum
33
34 120 of the all the carbohydrates determined was lower than the calculated total carbohydrate
35
36 121 (Table 1), which could be due to the calculation of total carbohydrate is overestimated and/or
37
38 122 to some carbohydrate components were not adequately quantified. Starch percentage was
39
40 123 between 42.6% and 58.7% found in Colorado and Raspinegro Canario landraces, respectively.
41
42 124 The mean concentration of starch (49.9%) was clearly lower than the values obtained by other
43
44 125 authors (ANDERSON et al., 2013; DI SILVESTRO et al., 2012; HAGER et al., 2012;
45
46 126 RAGAEI et al., 2006). Also, high amylose content was observed with a mean value of 37.5%
47
48 127 of starch and a range between 34.1% and 44.3% of starch found in Colorado and Español
49
50 128 landraces, respectively. These data are similar that those reported by BLAZEK and
51
52 129 COPELAND (2008) but are higher than indicated by HAGER et al. (2012). Positive
53
54 130 correlations ($P<0.001$) were observed between starch, amylose and sucrose. Sucrose
55
56
57
58
59
60
61
62
63
64
65

131 concentration increased when the starch content increased which could be due to the sucrose
132 is mostly produced for the hydrolysis of starch. In contrast, inverse correlations were observed
133 between starch with protein ($r=-0.534$, $P<0.01$) and moisture ($r=-0.459$, $P<0.01$). These
134 correlations could be explained for the dilution effect of the starch on the concentrations of
135 water and protein. Dietary fibre concentration varied between 13.4% obtained in Arisnegro
136 velloso de grano blanco and above 18% in the Raposo, De la tierra, Español and Jallado
137 landraces. The content of fibre was similar to data showed by DI SILVESTRO et al. (2012),
138 slightly higher than those reported by RAGAEE et al. (2012) and ANDERSSON et al. (2013)
139 and considerably higher than other values found in the literature (KANDLAKUNTA et al.,
140 2009; RANHOTRA et al., 1996). It is a well known that during the storage of starchy foods
141 resistant starch is produced (ANDERSON et al., 2013; RAGAEE et al., 2006). There two
142 relevant factors influencing the formation of resistant starch, temperature applied and
143 proportion of amylose. Our samples were desiccated at 105 °C and they contained high
144 amounts of amylose, which favour the formation of resistant starch (ÅKERBERG et al., 1998;
145 LEEMAN et al., 2006; VAN HUNG et al., 2008). Like soluble fibre, resistant starch has
146 interest in the maintenance of colonic health (ÅKERBERG et al., 1998). Also, food products
147 rich in resistant starch frequently result in low glycaemic and insulinaemic responses
148 (GRANFELDT et al., 1995). Insulin resistance syndrome is increasingly considered as a
149 potential risk factor for the development of a number of diseases such as obesity, diabetes and
150 atherosclerosis (ÅKERBERG et al., 1998). So, the consumption of wheat landraces with trend
151 to produce resistant starch could be of interest in the prevention of these diseases
152 (ÅKERBERG et al.; LEEMAN et al., 2006).

153 The fructose content detected in all the analyzed landraces varying between 0.53% and
154 0.84% for Colorado and Isla de Fuerteventura landraces, respectively. The sucrose was the
155 predominant sugar in the samples of wheat grain. Plaganudo landrace had the highest content

156 of sucrose (1.86%), while Colorado landrace presented the lowest sucrose concentration
157 (0.84%). The sum of the sugars is in agreement with other data reported in the literature
158 (ANDERSSON et al., 2013; SERENA and KNUDSEN, 2007).

159 The consumption of 100 g of whole-wheat flour represents 22.3% and 27.1 % of the
160 recommended dietary intake (RDA) of proteins for male (56 g/day) and female (46 g/day)
161 adults, respectively. Wheat grains are a very good source of complex carbohydrates; so, the
162 consumption of 100 g de wheat represents a 38% of the RDA (130 g/day) for total digestible
163 carbohydrates. The fibre intake for the 100 g of wheat accounts for 64.8% and 42.6% of the
164 RDA intake (FOOD AND NUTRITION BOARD, 2005) for female and male adults,
165 respectively, while the fat intake is very low. There is no recommended dietary intake for
166 phenolic compounds. However, the American Cancer Society (KREBS-SMITH et al., 1995)
167 has established 100 mg/day of flavonoids as an adequate amount for the prevention of cancer
168 and other degenerative illnesses. The consumption of 100 g of the wheat landraces studied
169 represents a 63.1% of the adequate intake for total phenolic compounds.

170 Many significant differences were found in the mean concentrations physicochemical
171 parameters between the two species of wheat considered (*Fig. 1.A and B*). The samples of *T.*
172 *aestivum* specie had higher ($P<0.05$) mean moisture, protein and fibre and lower ($P<0.05$)
173 mean starch, sucrose, and amylose concentrations than those samples belonging to *T.*
174 *turgidum*. Also, mean total phenolic compounds, ash, fructose and acidity (with a lower pH
175 mean value) were higher in the samples belonging to *T. aestivum*, although without
176 significant differences ($P>0.05$). Mean concentrations of the physicochemical parameters
177 analyzed were determined in the two subspecies included in *T. aestivum* (*spp. vulgare* and
178 *spp. compactum*) and in *T. turgidum* (*spp. durum* and *spp. turgidum*), respectively (data no
179 shown). The *spp. compactum* belonging to *T. aestivum* showed higher ($P<0.05$) mean fibre,
180 amylose and acidity concentrations and lower ($P<0.05$) mean moisture and fat concentrations

181 than the *spp. vulgare* Similar physicochemical characteristics were observed in both
182 subspecies of *T. turgidum*. Only the mean fibre content of the *spp. turgidum* was higher than
183 that mean content in the *spp. durum*.

185 **3. Conclusions**

186 There are differences in the proximate composition and pH and acidity between the cultivars,
187 species and subspecies of wheat analyzed. Low contents of starch and fibre suggest the
188 transformation of starch in resistant starch in the storage and desiccation process. The high
189 proportion of amylose could favour this transformation. An important contribution of
190 complex carbohydrates including fibre, protein and phenolic compounds was observed for the
191 consumption of wheat.

193 **Acknowledgements**

194 This work was financed by a research contract in the European Project Interreg III B
195 "Germobanco Agrícola de la Macaronesia". We also gratefully acknowledge the help of
196 Patrick Dennis for revising and checking the English in this paper.
